METHOD FOR THERMAL CRYSTALLIZATION OF PREFORM NECK

Technical Field

5 [0001] This invention relates to a method for thermal crystallization of the neck of a synthetic resin preform.

[0002] Patent Document 1 describes a biaxially drawn, blow molded bottle made of a resin of polyethylene terephthalate (hereinafter referred to as a
10 PET) resin to be used with such products as tea and juice that require a filling operation at a high temperature or a thermal treatment process including sterilization. If a PET resin bottle is to be filled with tea, juice, or one of other products that require hot filling (at a temperature in the range of 80 to 90°C) or a thermal treatment process, then use is made of a so-called heat-resistant
15 neck which has a property of heat distortion resistance that has been improved by thermal crystallization process. Patent Document 2 describes a method for thermal crystallization treatment.

[0003] Fig. 5 is an explanatory diagram showing an example of equipment
20 for thermally crystallizing the neck 2 of a PET resin preform 1. The injection-molded preform 1 is inserted into the holder 22, and the neck 2 is heated with an infrared heater 21 to undergo the thermal crystallization process. At that time, the holder 22 is rotated so that heating would be uniform in the circumferential direction.

25 [Patent Document 1] Application No. 1998-058527
[Patent Document 2] Publication No. 1986-24170

[0004] Meanwhile, as shown in Fig. 6, there is a thermal crystallization method, which involves loading a jig of an inverted support type with the
30 preform 1. This method utilizes an air chuck, which makes it easy to load the jig 11 with the preform 1 or to unload the preform 1 therefrom. The machinery and equipment are simple and able to give improved productivity.

[0005] The preform 1 is kept uninclined in its inverted posture on the jig 11
35 of the above-described inverted conveying type by the contact between preform top surface 2a (top surface in its upright posture) and top surface 12a of jig base 12, and by the support of a guide cylinder 18 standing upright from the jig base 12 of the jig 11.

[0006] However, if the preform is treated for thermal crystallization by using the jig of the above-described inverted support type, problems arise in that the neck measurements fail to have the values as previously designed, that especially, the outer diameter tends to be larger than the designed value, or that the upper end of the neck 2 has a horn aperture in an extreme case. These problems have to be solved.

[0007] A technical problem of this invention is to find out the cause of above-described problems and to create a method for thermal crystallization by means of a jig of the inverted support type that enables a preform neck to be obtained with high dimensional accuracy. The object of this invention is to provide a highly productive thermal crystallization process for the bottle neck and an efficient biaxial drawing and blow molding process for the bottle.

Means of Solving the Problems

[0008] The method according to Claim 1 of this invention to solve the above-described technical problems is a method for thermal crystallization of the neck under the conditions that the jig of the inverted support type is loaded with a synthetic resin preform for use in the biaxial drawing and blow molding process and that the inverted preform is installed on the jig so that a gap is formed under top surface of the neck of said preform .

[0009] The inventors studied the problems and found the reasons why outer diameter tends to be larger than the designed value and why the upper end of the neck gets the shape of a horn aperture. As the main reason, they have found out that the neck shrinkage caused by thermal crystallization has been inhibited by the friction between top neck surface and top jig base surface. The load acting on the plane of contact is the weight of the preform itself, which is a relatively small load. However, the inventors discovered that this friction has become large at the top neck surface and inhibited the shrinkage because the preform is heated at a thermal crystallization temperature in the range of 150-220 degrees C, which is considerably higher than the softening temperature (or glass transition temperature) of the PET resin. Thus, the inventors have come to invent the method of Claim 1.

[0010] The basic concept of Claim 1 is that the preform neck is thermally crystallized by installing the bottle on the jig under the condition that a gap is maintained under the top neck surface. Because of this gap, the thermal crystallization can be carried out, with no contact of the top neck surface with

a part of the jig, such as the top jig base surface or jig parts, and no friction-caused inhibition of thermal shrinkage. Thus, the top neck surface can be prevented from having a wrong shape, such as a horn aperture.

5 [0011] The method according to Claim 2 of this invention comprises that, in the invention of Claim 1, a gap is formed under the top neck surface of inverted preform by using a jig provided with an upright support unit and by inserting the support unit into the preform along the central axis to the limit of insertion determined previously by the contact of a portion of the support
10 unit with a certain inner wall portion of the preform so that the inverted preform can be fitted to the jig.

[0012] The method of Claim 2 is a practical method for allowing a gap to be formed under the top neck surface. This method comprises forming a gap
15 under the top neck surface by allowing the upright support unit of the jig to come in direct contact with an inner wall portion, such as the body or the bottom, of the preform. It is also a method for carrying out thermal crystallization while holding the preform in an inverted posture.

20 [0013] The direct contact of the support unit with the inner wall portion of the preform sets the limit to the insertion of the support unit into the preform. Because of this contact, the preform can maintain its inverted posture without allowing the top neck surface to contact with the top jig base surface. Therefore, thermal crystallization can be processed with no frictionally caused
25 inhibition of thermal shrinkage, and the neck has precise diameter and shape as designed.

[0014] There are some cases of thermal crystallization process in which a bore diameter control device, such as a control core in a columnar shape or a
30 control ring in a cylindrical shape, is fitted in the neck in direct contact with the inner wall of the neck. This device is used to increase the dimensional precision or to prevent the neck from being distorted into an elliptical shape. In this invention, too, a control ring can be fitted around an area of the support unit located at the height in which the support unit faces opposite the preform
35 neck, and can be used as a bore diameter control.

[0015] The method according to Claim 3 of this invention comprises that the method of Claim 2 is applied by allowing the end portion of the support unit to come in direct contact with the inner wall of the preform bottom.

[0016] The above method of Claim 3 makes it possible for the preform to be held by, e.g., an air chuck and to fall free from above the support unit. Thus, the inner wall of the preform bottom is contacted with the end portion of the support unit. In this way, the preform can be installed easily on the jig in the inverted posture while preventing the top neck surface from touching the top jig base surface.

[0017] If the end portion of the support unit is given a semi-spherical shape in accordance with the shape of inner wall of the preform bottom, then the inverted preform, once fitted to the jig, can be held firm in the vertical direction during the conveying or thermal crystallization process, as long as this end portion is kept fitly in touch with the inner wall of the preform bottom.

[0018] The method according to Claim 4 of this invention comprises that, in the invention of Claim 2, the support unit at its given height is contacted with a given area of the inner peripheral wall of the preform body.

[0019] The above method of Claim 4 is a method in which the support unit is contacted peripherally with a prescribed zone of inner wall of the preform body. Because of this peripheral contact of the support unit with the body, the preform can maintain a good posture stably.

[0020] The method according to Claim 5 of this invention comprises that, in the invention of Claim 4, the support unit has a tapered portion at a given height and that this tapered portion narrows toward the top end and comes in contact peripherally with the inner wall of a tapered portion of the preform body. This tapered preform portion is disposed in the upper area of the body and becomes narrow for some length toward the bottom.

[0021] For the purpose of controlling the wall thickness distribution in the blow molded bottles, the preform has a tapered portion in the upper area of the body where the body becomes narrow for some length toward the bottom. The method of Claim 5 utilizes this tapered portion to enable the support unit to be contacted with the preform body peripherally.

[0022] The tapered portion formed in the area of a given height of the support unit can be contacted directly with the tapered portion of the preform in the upper area of the preform body. In addition, both tapered portions can be positioned closely opposite each other. That is, a part of the tapered portion formed in the area of a given height of the support unit can be fitted into the

tapered portion of the preform in direct contact with the inner wall of the preform body. In this position, the preform can be held stably in a good posture.

5 [0023] The method according to Claim 6 of this invention comprises that, in the invention of Claim 2, a jig having a bore control device is used, and that this bore control device is used as the support unit by fitting this device into the neck in direct contact with the inner neck wall.

10 [0024] There are cases of thermal crystallization process where a bore diameter control device, such as a columnar control core or a cylindrical control ring, is used to obtain a precise bore diameter of the neck after shrinkage under the condition that such a device is fitted into the neck in direct contact with the inner wall of the neck (or in some cases, with a possible clearance
15 between the control device and the inner wall). The method of Claim 6 utilizes this bore diameter control device without making use of a separate support unit, so that this device functions as the support unit.

[0025] The method according to Claim 7 of this invention comprises that, in
20 the invention of Claim 1, 2, 3, 4, 5, or 6, the preform is made of a PET-related resin.

[0026] Because the PET-related resin preform is in the amorphous state, the resin softens to a large extent, and the friction increases greatly between the
25 top neck surface and the top jig base surface, when the neck is thermally crystallized at a high temperature. Therefore, operation of the invention concerning the prevention of inadequate deformation of the neck becomes more effective than ever when the thermal crystallization is carried out under the condition that a gap is formed under the top neck surface of the inverted
30 preform. Thus, the PET-related resin bottles are widely used with tea, juice, etc., that requires filling at a high temperature (in the range of 80 to 90 degrees C), or used in those applications requiring thermal treatment processes. The method of Claim 7 provides a PET-related resin preform and a resultant bottle, which have no inadequate deformation caused by thermal
35 crystallization and have a heat-resistant neck made with dimensional accuracy.

[0027] PET resin is mainly utilized in Claim 7 of this invention as the PET-related resin. However, as long as the essential qualities of the PET resin are not damaged, copolymer polyesters can also be used, which comprise a major
40 part of ethylene terephthalate units combined with other polyester units. As

the components for use in copolymer polyesters there may be mentioned dicarboxylic components, such as isophthalic acid, naphthalene-2,6-dicarboxylate, and adipic acid; and glycolic components, such as propylene glycol, 1,4-butanediol, tetramethylene glycol, neopentyl glycol, cyclohexane dimethanol, and diethylene glycol.

And for example, nylon resins, polyethylene naphthalate resins can be blended with the PET to improve, e.g., heat resistance.

[0028] In addition, the PET-related resin bottle of this invention may have an intermediate layer, such as a nylon resin layer, in a combination of layers comprising, e.g., a PET resin – a nylon resin – a PET resin, to give the bottle an improved gas barrier property.

Effects of the Invention

[0029] This invention comprising above-described methods has the following effects: In the method of Claim 1, the preform neck is thermally crystallized by installing the bottle on the jig under the condition that a gap is maintained under the top neck surface of the preform. Because of this gap, the thermal crystallization can be carried out with no friction-caused inhibition of thermal shrinkage. Thus, the top neck surface can be prevented from having a wrong shape, such as a horn aperture.

[0030] In the method of Claim 2, the support unit standing from the jig base is contacted with a prescribed inner wall of the body or the bottom of the preform. Thermal crystallization is carried out under the condition that the preform is held in the inverted posture while a gap is maintained under the top neck surface of the inverted preform. This method makes it possible for the bottle neck to have the precise bore diameter and shape as previously designed, with no friction-caused inhibition of thermal shrinkage in the top neck portion.

[0031] In the method of Claim 3, the end portion of the support unit is contacted with the inner wall of the preform bottom.

This method enables the preform to be installed easily on the jig in the inverted posture.

[0032] In the method of Claim 4, the support unit is contacted peripherally with a prescribed area of inner wall of the preform body. Because of such peripheral contact of the support unit with the body, the preform can maintain a good posture stably.

[0033] In the method of Claim 5, the tapered portion in the upper area of the support unit can be contacted directly with the tapered portion in the upper area of the preform body. In addition, both tapered portions can be positioned
5 closely opposite each other. That is, a part of the tapered portion in the upper area of the support unit can be fitted into the tapered portion of the preform in direct contact with the inner wall of the preform body. In this position, the preform can be held stably in a good posture.

10 [0034] The method of Claim 6 utilizes a bore diameter control device so that this device functions as the support unit.

[0035] Because the PET-related resin preform according to Claim 7 of this invention is in the amorphous state, the resin softens to a large extent, and the
15 friction increases greatly between the top neck surface and the top jig base surface, when the neck is thermally crystallized at a high temperature. Therefore, operation of the invention concerning the prevention of inadequate deformation of the neck becomes more effective than ever when thermal crystallization is carried out under the condition that a gap is formed under
20 the top neck surface of the inverted preform. The method of Claim 7 provides a PET-related resin preform and a resultant bottle, which do not have any inadequate deformation caused by thermal crystallization but have a heat-resistant neck made with dimensional accuracy.

Preferred Embodiments of the Invention

25

[0038] This invention is further described with respect to preferred embodiments, now referring to the drawings. Fig. 1 is a vertical sectional front view of jig 11 in the first embodiment of this invention, with preform 1 installed thereon. The jig 11 is used for thermal crystallization of the preform neck made of a PET resin.

30

[0039] The jig 11 comprises a cylindrical jig base 12, which has a top surface and is fitted to a conveying system (not shown), and also a support unit 13 standing along the central axis from the central portion of the top surface of the jig base 12. In the first embodiment, this support unit 13 comprises a support base 14 screw-engaged with the jig base 12, a support rod 15 screw-engaged with the support base 14, and a spherical end portion 16 screw-engaged with the support rod 15. The entire height of the support unit 13 is adjustable by means of double nuts 16a.

40

[0040] As obvious from Fig. 1, the semi-spherical end portion 16 comes in contact with the inner wall of the bottom 4 of the preform 1 under the condition that the preform 1 has been fitted from above to the jig 11. At that time, a gap G is formed between the top surface 2a of the neck 2 and the top surface 12a of the jig base 12. With the semi-spherical end portion 16 in direct contact with the bottom 4 of the semi-spherical shell shape, the preform 1 can be held stably in the inverted posture.

[0041] Thermal crystallization is carried out under this condition by using an infrared heater. The top surface 2a of the neck 2 is not in contact with the top surface 12a of the jig base 12, and the thermal crystallization makes the neck 2 shrink in a free state. Thus, the neck 2 has the precise diameter in conformity to the given design standard.

[0042] Fig. 2 shows the second embodiment of the jig used in thermal crystallization. This jig 11 comprises a cylindrical bore diameter control device 17, which is fitted around the support base 14 of the jig 11 of Fig. 1. Thus, the jig 11 of Fig. 1 can optionally be equipped with such a bore diameter control device 17.

[0043] The bore diameter control device 17 is utilized by fitting it into the neck 2 in direct contact with the inner wall of the neck 2, or by fitting it in the neck 2 so as to have some clearance to minimize the residual distortion caused by thermal crystallization. In either way, this bore diameter control device 17 ensures that the preform 1 is held stably in its inverted shape.

[0044] Fig. 3 shows the third embodiment of the jig used in thermal crystallization. A tapered portion 5 in the upper area of the body 3 of the preform 1 is utilized in this embodiment. A tapered support portion 13a narrows toward the top end of the support unit 13. This tapered support portion 13a is contacted peripherally with the inner wall of the tapered portion 5, which has been formed in the upper area of the body 3 of the preform 1 and narrows partly toward the bottom 4.

[0045] In this state of contact, a gap G is formed between the top surface 2a of the neck 2 and the top surface 12a of the jig base 12. A part of the slope of the tapered portion 13a of the support unit 13 can be positioned opposite and close to a part of the slope of the tapered portion 5 of the preform 1. That is, a part of the tapered portion in the upper area of the support unit 13 can be fitted to the tapered portion 5 of the preform 1 in direct contact with the inner

wall of the preform body 3. Because of this zone of contact, the preform 1 can be held stably in its inverted posture.

5 [0046] The cylindrical bore diameter control device 17 can also be used in the above-described third embodiment, just as used in the second embodiment, by fitting the device 17 around the support unit 13. A solid support unit 13 has been used in the third embodiment, but for the purpose of weight saving, a hollow support unit 13 can also be used.

10 [0047] Fig. 4 shows the fourth embodiment of the jig used in thermal crystallization. Although the jig 11 has also a cylindrical bore diameter control device 17, the upper portion of this device 17 extends in a tapered manner so that the device 17 is given a function as the support unit 13.

15 [0048] The state of contact in the fourth embodiment is roughly similar to that found in the third embodiment. The tapered portion 17a of the bore diameter control device 17 is contacted peripherally with the tapered portion 5 of the preform 1, and a gap G is formed between the top surface 2a of the neck 2 and the top surface 12a of the jig base 12. Like in the third embodiment, a
20 part of the slope of the tapered portion 17a of the bore diameter control device 17 (support unit 13) can be positioned opposite and close to a part of the slope of the tapered portion 5 of the preform 1. In addition, the portion corresponding to the bore diameter control device 17 is in a position fitted to the neck 2 in direct contact with the inner wall of the neck 2. These double
25 zones of contact ensure that the preform 1 is held stably with no inclination to the inverted posture during the conveying process or during the period when the preform 1 is rotated for uniform heating in the thermal crystallization process.

30 [0049] The preferred embodiments of this invention have been described with respect to a PET resin preform, which is processed by the method of this invention. However, this invention is not limited to the preform of the PET-related resins. The action and effect of this invention are also generally brought about in the resin preform of polypropylene series, polyethylene
35 naphthalate series, and other resins.

Industrial Applicability

40 [0050] As described above, the method of this invention for thermally crystallizing the preform neck ensures that after the processing, the neck has

the precise diameter as previously designed even if the preform is treated on the jig of an inverted conveying type. This method also makes it easy to design the thermal crystallization process for the preform, the preform-conveying process, and the biaxial drawing and blow molding process. On the whole,
5 highly productive processes can be attained.
